ABSTRACT

Cervical cancer is the second leading cause of female cancer in India. Human papilloma virus (HPV) infection is the most important risk factor for uterine cervical neoplasms. HPV oncogene expression can be detected by cellular protein p16 (INK4a) using immunohistochemistry. The present study aims to assess the immunoreexpression of protein p16INK4a in cervical dysplastic and neoplastic lesions. The study includes 86 cases of premalignant and malignant cervical lesions diagnosed on histopathology for two years. All cases were subjected to p16 INK4a immunohistochemical staining. 72% of cases (62 out of 86) (including premalignant and malignant) were positive for p16. P16 was positive in 88% of invasive carcinoma, 70.83% of HSIL and 40% of LSIL. Cervical cancer is associated with HPV infection which can be identified by overexpression of p16 INK4a in premalignant and malignant lesions. The expression of p16 INK4a positivity increases with increasing grades of dysplasia and thus helps in the stratification of cervical dysplastic and neoplastic lesions. P16 INK4a can be used as a surrogate marker of HPV infection.

1. Introduction

Cancer of the cervix uteri is the 4th most common cancer among women worldwide¹ and ranks as the 2nd leading cause of female cancer in India.² HPV causes the majority of cervical cancer cases. Human genomic integration of the high-risk HPV viral genome causes up-regulation of the tumor suppressor gene P16INK4A. The protein p16 is integral to pRb (Retinoblastoma) mediated G1-S phase transition of the cell cycle which acts by inactivating the CDKs that phosphorylate Rb protein. Reciprocal relation between p16 and pRb was noticed. The E7 protein of the Human papillomavirus binds and inactivates Rb which leads to the release of E2F, a transcription factor, which in turn can turn on the genes required for entry into the S phase of the cell cycle. This augments the levels of p16 through a negative feedback mechanism. Accumulation of E2F has also been found to increase P16 transcription.^{3,4}

The protein p16INK4a serves as a surrogate marker for the oncogenic activities of HPV in replication-competent cells of cervical epithelium, and its overexpression is well established in cervical intraepithelial neoplasia (CIN) and invasive cancer by many studies.^{5,6} A potential biomarker should distinguish between cervical intraepithelial Neoplasms (CIN) and other non-neoplastic cervical lesions. HPV detection can be done using p16INK4a as a diagnostic marker by immunohistochemical staining method to show the varied intensity and expression in increasing grades of uterine cervical dysplasia and malignancy.⁷

2. Materials and Methods

In this prospective study from July 2016 to June 2018, total number of 86 cases of uterine cervical premalignant lesions and malignant neoplasms diagnosed in the Department of Pathology, Siddhartha medical college, Vijayawada were included. All the specimens obtained were fixed in 10%

buffered formalin and were submitted in Toto for routine tissue processing. Paraffin-embedded tissues were sectioned and stained with Haematoxylin and eosin. All 86 Cases were selected for IHC to detect the intensity of HPV. For Immunohistochemistry, paraffin-embedded tissue sections were floated on chromalum coated slides. The antigen retrieval was done by using Tris buffer. The sections were stained using a standard peroxidase- antiperoxidase technique. The slides were incubated with primary monoclonal antibody- p16 (a mouse monoclonal anti-p-16 antibody, Fremont, CA, Biogenex, USA) for one and a half hours. The chromogen used was DiaminoBenzidine (DAB), after incubation with secondary polymer antibody for 30 minutes, counterstaining was done with Haematoxylin and coverslipped. The p16 immunostaining was considered positive when the nucleus and or cytoplasm took brown colour in at least 1% of tumor cells. Different methods had been used for scoring p16 immunostaining in several studies. However, the following parameters were considered in the scoring of p16 positive cells in the present study. Scoring was semi-quantitative based on the following. The intensity of staining was graded between 0-3. (Table 3). Negative –Grade 0, Weak focally positive – Grade 1+, Moderate – (Weak, diffusely positive or strong focally positive) – Grade 2+, Strong – (strong diffusely positive) – Grade 3+. Grade 0 was considered negative for p16INK4a staining, while Grade 1 to Grade 3 were considered positive for p16INK4a. p-value was calculated for various premalignant lesions, and invasive carcinoma versus p16 expression using the chi-square test and p-value obtained was <0.05 which is statistically significant.

3. Results

The study included 86 cases of cervical dysplastic and malignant lesions. The most common lesion was Squamous cell carcinoma (35 cases, 40.60%), followed by HSIL (24 cases, 27.9%), LSIL (20 cases, 23.25%), adenocarcinoma (6 cases, 6.97%), and adenosquamous carcinoma (1 case, 1.16%) (Table 1).

Table 1: Case distribution in the present study

Lesion	Number of cases
LSIL	20(23.25%)
HSIL	24(27.9%)
Carcinoma	42(48.83%)
Total	86

Table 2: p16INK4a expression in total cases

Types	LSIL	HSIL	Carcinoma
Positive	8 (40%)	17 (70.83%)	37 (88.09%)
Negative	12 (60%)	7(29.16%)	5 (11.9%)
Total	20	24	42

4. Discussion

In the present study, there were 20 cases of LSIL, 24 cases of HSIL and 42 cases of invasive cervical carcinoma in histopathology. Among them, p16INK4a was found to be positive in 8 cases of LSIL, 17 cases of HSIL and 37 cases of cervical Carcinoma (Table 2). The percentage of overall p16 positivity in this study was 72.09% which was close to that of Chaloob et al. (74.28%) and Supriya et al. (76.1%). Many studies have emphasized the significance of using p16INK4a immunostain as a marker for identifying dysplastic and neoplastic lesions caused by high-risk HPV.⁸ The staining intensity of p16INK4A varies with the amount of dysplasia. As the grade of dysplasia increases, there is an increased expression of p16INK4A.^{9,10} In this study, most of the LSIL cases were p16INK4a negative (60%). The high percentage of negativity of p16INK4a in LSIL may be due to latent or subclinical HPV infection with a low viral load that may be insufficient for p16INK4a expression. The other possible reason for the lower expression of p16INK4a in LSIL may be because a certain percentage is thought to be caused by low-risk HPV types.¹¹ Previous studies indicated that viral oncoprotein of low-risk HPV such as HPV-6 does not affect p16INK4a because the affinity of HPV-6 E7 protein for cellular pRb is ten-fold lower than that of HPV-16 E7 for pRb.¹²

In this study, 70.83% of HSIL and 88.09% of cervical carcinomas show p16INK4a over-expression, which emphasizes the important causal relationship between HPV and cervical cancer. However, a few patients with HSIL and cervical cancer had p16INK4a negativity respectively. The possible explanation for the absence of p16INK4a expression in these high-grade lesions could be methylation of the p16INK4a promoter resulting in silencing of the p16 INK4A gene.¹³ These findings were similar to those of study by Umar et al (HSIL-81.81%, Carcinoma- 88.52%) which also found that p16^{INK4A} expression was directly related to the increasing grade of CIN.⁹

p16 is primarily a nuclear protein, and hence immunohistochemical expression should show nuclear staining. However, in dysplasia, both nuclear and cytoplasmic staining is observed possibly because of post-transcriptional modification or overproduction of p16 protein forcing its transfer into the cytoplasm.¹⁴ Among p16-positive cases, this study identified a direct relationship between lesion severity and reaction intensity. The frequency of positive cells and the reaction intensity were statistically significantly different when compared among different histological groups. The immunoreactivity for p16 in squamous cell carcinoma is unequivocally shown by all studies to date and has been confirmed by this study as well (Table 4).

Table 3: Intensity of p16INK4a staining

Category	The intensity of p16INK4a staining			
	0 (Negative)	1+ (Weak)	2+ (Moderate)	3+ (Strong)
LSIL	12(60%)	6(30%)	2(10%)	0
HSIL	7(29.16%)	5(20.83%)	8(33.33%)	4(16.66%)
SCC	4(11.42%)	0	10(28.57%)	21(60%)
Adenocarcinoma	1(16.66%)	0	1(16.66%)	4(66.66%)
Adenosquamous carcinoma	0	0	0	1(100%)
Total	24	13	22	27

Table 4: Various studies on P16INK4A - positive expression in CIN & Carcinoma

Author	Year	Normal	CIN I(LSIL)	HSIL		Carcinoma
				CIN II	CIN III	
Kumari K	2013	25% (4/16)	62.5% (10/16)	75% (12/16)	81.2% (13/16)	100% (16/16)
Umar et al	2016	0% (0/5)	0% (0/6)	80% (4/5)	83.33% (5/6)	88.52% (54/61)

Present study	2018	Not included	40% (8/20)		70.83% (17/24)	88.09% (37/42)

Fig. 1: Histopathological section showing (a) LSIL, (b) HSIL & (c) SCC (H&E, x4), IHC expression of p16INK4a in (d) LSIL, (e) HSIL & (f) SCC (p16, x4)

5. Conclusion

The neoplastic transformation of cervical epithelial cells by HPV can be detected by p16INK4a expression. Overexpression of the protein p16INK4a is a characteristic feature of dysplastic and neoplastic cervical epithelial cells. The expression of P16INK4a positivity increases with increasing grades of dysplasia (Carcinoma>HSIL>LSIL). P16 negative high-grade lesions also exist as reported by Valgareva et al (2004). Henceforth, our study reiterated that the protein p16INK4a can be used as a specific diagnostic marker of cervical dysplastic and neoplastic lesions.
